

ML Anti-Cheat Project: Current Challenges & Next Steps

Hello,

I would like to discuss the following ongoing issues and next steps regarding the ML Anti-Cheat project:

1. AWP Flick Shots (False Positives)

The model currently flags most AWP shots as suspect. Because the AWP requires rapid flicking motions, these legitimate, high-velocity crosshair movements are being misinterpreted by the model as aimbot-like behavior.

2. Silent Aim and Micro-Adjustments

While the model successfully detects standard aimbot patterns, it struggles to identify "silent aim" or low-FOV cheats. These cheats use very small micro-adjustments to the crosshair which currently blend in with normal player movements and bypass our detection.

3. Bunnyhop (Bhop) Detection Implementation

We need to outline the next steps and technical requirements for implementing a reliable bunnyhop script detection module to expand the anti-cheat's capabilities.

4. Impact of Real-Time Server Infrastructure

I am planning to implement real-time detection using a self-hosted dedicated server with CounterStrikeSharp. A key question is whether migrating to this direct data-gathering method will provide higher quality/frequency data that could naturally resolve the AWP and Silent Aim issues mentioned above.

5. Computer Vision / Image Processing Integration

Based on a recent video by Haix ("AI Overwatch Vs CS2 Cheaters - Who Wins?"), I am exploring the feasibility of integrating Image Process Recognition into our anti-cheat. I would like to discuss if implementing such a system is viable in terms of cost and performance, and how we might combine it with our current telemetry-based approach. [video ytb link](#)

He says in the video that this type of approach requires a lot of money. And by using img processing, he can detect also wallhack. I think on the actual approach you cannot detect wallhack not even that type of wallhack where you clearly look through the walls, because i don't think we can have a flag feature that states there is a wall there when the crosshair is pointing exactly to the enemy player and also the model records only kills(in a small window of ticks)
